The Viability of the Welfare State

James J. Heckman

Preliminary Draft, Subject to Revision

Prepared for World Justice Forum,
Vienna, July 2-5, 2008

*This research was supported by grants from the American Bar Foundation and the Hewlett Foundation to support work for the World Justice Forum. This paper draws in part from a paper presented at the OECD Conference in Toronto on the 2006 Jobs Report (Heckman, Ljunge, and Ragan, 2006).

I. Introduction

The welfare state is a late 19th-century invention. A lot has been written about it—pro and con. The case for the welfare state is that it protects its citizens against the consequences

of risks beyond their control.\textsuperscript{2} The case against the welfare state is that it blunts incentives and reduces productivity.

The economic performance of many welfare states has been poor. There has been a rapid run up in unemployment in most Western European welfare states in the past 20 years. When properly measured, many Western European welfare states have much higher rates of unemployment than are reported in the official statistics. Incentives to withdraw from work, to go underground, to evade taxes, to retire early and not to produce are high.

Immigration levels are also high in many European countries. There are serious problems with immigrant assimilation created in part by welfare state policies. There is slow growth in human capital—a vital ingredient for a modern economy. In addition, there are low rates of business formation, weak incentives for entrepreneurship and low levels of research and development. There are high taxes on labor and, in many countries, on capital. Poverty traps are often created that discourage work.

The forces creating the pressure on the welfare state are globalization and an inability to tax internationally mobile factors of production. The increase in the unpredictability in trade and technology, the increasing openness of economies and the secular bias against unskilled labor in trade and technology are also the forces that create the demand for the welfare state as an insurer against risk, and as a protector against the reduced wages that the unskilled experience when the demand for their skills is reduced. As economies become more open, it is much more difficult to shelter workers and firms from the rigors of the market. And in fact, less sheltered economies like the U.S. and U.K. have shown substantial increases in wage inequality and social inequality due, in part, to these trends.

In the current environment, a premium has emerged for flexibility and responsiveness of economies. High levels of workforce skill and a regulatory environment that supports change allow economies to benefit from new opportunities. An economic order that was well adapted to the more stable and predictable environment of the 1950’s and 1960’s and that had a large role for unskilled labor to play has become dysfunctional in the early 21\textsuperscript{st} century. The opportunity cost of security and preservation of the status quo—whether it is the status quo technology, the status quo trading partner or the status quo job—has risen greatly in recent times. While reforms have been made in Europe, they have mostly been small scale in nature. Europe has to run and not walk to keep up with the pace of global change, and it is barely even walking, although by European standards, it is rapidly reforming.

Not all welfare states have lagged, or at least they have not all lagged in the same way. It is fruitful to examine differences in economic performance among different welfare states. This is the topic of the paper. The key to a successful welfare state lies in devising proper incentives to encourage actors at all levels of the economic system to respond to the new opportunities. In principle, a welfare state can provide the proper incentives for productivity and at the same time afford a measure of security and dignity for its citizens. But it has to respect the operation of incentives.

\textsuperscript{2}See Agell (1999).
The Viability of the Welfare State

II. Themes of this paper

This paper develops five broad themes. First and foremost, people respond to incentives, and their responses are often very strong. It is very dangerous in designing laws and regulations to underestimate the ingenuity of economic agents in pursuing their self interest.

Second, the debate about the welfare state often poses a false dichotomy. It compares the U.S. (or the Anglo-Saxon bloc of countries) to Europe. It frames the debate as a choice among systems in place. The U.S., Canada, the U.K., Australia, and New Zealand are, of course, welfare states. They have made their share of mistakes in devising incentives and protecting their workers. The relevant issue is \textit{not} whether Europe should adopt the Anglo-Saxon model, or whether the Anglo-Saxons should adopt the European model. Rather, it is which features of the welfare state reduce inequality and provide insurance against uncertainty in an efficient way.

Third, the term “welfare state” is far too broad. At least four models are often mentioned (see Sapir, 2006) and these categories are surely too crude. (1) There is the Nordic/corporatist model (Scandinavia, Finland, Netherlands), which provides high level of security for workers, heavy reliance on active labor market policies, low inequality, high levels of taxation of labor income, relatively low levels of taxation of capital income, very high levels of education and high levels of government activity, generous grants that are not means tested, high levels of wage compression, centralized unions and high levels of concentrated unions and wage setting.

Then there is the Continental model (Austria, Belgium, France, Germany and Luxembourg). Its features are heavy reliance on insurance-based nonemployment benefits and old-age pensions, strong unions that are not all centralized, lots of regulation, inflexibility in labor markets and compressed wage distributions. It shows a marked inability to adjust to change.

A third model is the Mediterranean model (Italy, Spain, Portugal, Greece). It is characterized by reliance on employment protection (lifetime jobs), with union-covered sectors with compressed wages, concentrated spending on old-age pensions and high segmentation of entitlements and status.

Finally, there is the Anglo-Saxon model (United States, Canada, United Kingdom, New Zealand and Australia). It is characterized by social assistance only in the last resort, low levels of job protection and minimum wages, high levels of cross-section wage inequality, considerable social spending on old-age pensions, and high levels of segmentation of entitlements and status.

For close observers of the welfare state, these four categories are far too broad in many respects. For example, Ireland is a corporatist state often lumped into the Anglo-Saxon camp.\textsuperscript{3} It has strong incentives, especially for capital. It also has a lot of wage coordination. The four categories of welfare state are thus, at best, a rough cut.

Fourth, comparing alternative economic systems is a dangerous practice. Different baseline and terminal periods can produce very different ratings of the performance of any economy. Yesterday’s success is often today’s failure. Recall the love affair with the Dutch Polder model 10 years ago that still lingers on in some quarters. There was an even earlier

\textsuperscript{3}Ireland has centralized bargaining in trade unions.
fascination with Japan and, earlier yet, a fascination with the U.S.S.R.

Many European think tanks and the OECD have embraced the “Nordic model” or the closely related “corporatist model”. For example, the recent 2006 OECD Jobs Report (OECD, 2006), which updated the influential 1994 OECD Jobs Report (OECD, 1994), trumpets the “corporatist model” as being coequal in efficiency with the Anglo-Saxon model. An influential paper by Andre Sapir (2006) of the Bruegel Group made the same endorsement, and has had a big effect on the European discussion. This praise is echoed by Jeff Sachs (2006) in a recent column in Scientific American:

*Half a century ago, the free-market economist Friedrich von Hayek argued that a large public sector would threaten democracy itself, putting European countries on a “road to serfdom.” Yet the Nordic states have thrived, not suffered, from a large social welfare state, with much less public-sector corruption and far higher levels of voter participation than in the US... Von Hayek was wrong. In strong and vibrant democracies, a generous social-welfare state is not a road to serfdom but rather to fairness, economic equality and international competitiveness.*

Sweden’s economic performance in the past decade has been impressive. So has that of Finland. Denmark’s “flexicurity” system promotes job mobility. It gives generous unemployment benefits and, at the same time, provides sanctions to promote rapid return to work among the unemployed. It has attracted a lot of attention among the policy pundits. The recent fascination with Scandinavia is typical of a mentality of many policy analysts who look to a working model as a system for adoption, rather than looking at basic principles that transcend any economy to explain the successes and failures of a particular model. This paper looks at those basic principles to draw general lessons from many models rather than to extol the virtues of one system currently in place in comparison with any other system.

Fifth, I make a basic methodological point that affects the way analysts should use and interpret the available evidence. A large literature on the European welfare state relies on arbitrarily constructed indices to examine incentive effects of different policies. Many of these studies claim to prove that the incentives (“institutions”) that basic economic theory suggest should matter do not in fact matter. These conclusions are a statistical mirage. They are consequences of using bad data. When incentives are properly measured, they matter, and they matter a lot.

Students of Latin American labor markets have measured the costs of regulation more carefully than students of the European welfare state. Latin America has experienced more dramatic regime changes and policy shifts than any that have occurred in Europe. The Latin American data clearly show strong adverse effects of perverse incentives.

**III. The plan of the rest of the paper**

The rest of the paper proceeds in the following way. Given the current romance with Nordic and corporatist models, I look at their performance and the performance of welfare states more generally. It is useful to examine long-run trends to supplement the short-run time series that attract so much attention in policy discussions. Nordic performance is *not* impressive, especially if one looks at long run trends. Policies in place often *conceal* rather than solve problems and create problems for the future. Problems of flawed measurement create serious problems in making meaningful comparisons across alternative systems.
Long-run trends in skill accumulation, in attitudes toward work, in research and development, in adoption of new technology, benefit dependency, and dependence on government employment are not encouraging and portend serious problems in the future for many quarters of Europe, even for Scandinavian Europe.

IV. The performance of the European welfare state in the past 20 years

First consider the labor market. A new OECD Jobs report, released in 2006 (OECD, 2006), shows that some of the reforms suggested in the 1994 Jobs Report (OECD, 1994) have been implemented. It claims that those reforms partially account for the improved state of European labor markets. European unemployment rates post-1994 are lower but they are still very high. See Figure 1, which plots the “open” (official) unemployment rates over time. Starting in the early 1980s, the overall Western European OECD unemployment rate rose. It has not fallen to its previous level. However, unemployment appears to be much lower in corporatist Europe. This has led to calls by some to adopt the corporatist model as a way to conduct economic policy.

Figure 1: Open Unemployment Rates in the OECD.

Average productivity growth is lower in the EU than in the U.S. However, it is high in the “flex market” Nordic countries. See Figure 2.
The Viability of the Welfare State

Figure 2: Labor productivity growth in the business sector.

Source: OECD Reports.

However, GDP growth is lower in the past 5 years in the EU than in the U.S. This is true even for corporatist Europe. See Figure 3.

Figure 3: Real GDP Growth.

Source: OECD Reports.

Consider, in particular, the performance of one of the “Nordic miracle” countries—Sweden—the Nordic country most often studied. It has recently seen improvement in its economic performance after the deep recession of the early 1990s. However, its recovery is not strong. Placed in historical perspective, the story of Sweden is one of relative decline and a mild recent recovery. Figure 4 shows the decline in PPP—adjusted GDP per capita in Sweden as a percentage of the OECD average since the Second World War. Sweden has shown secular decline, which has only recently been arrested, and its recent boom is modest in historical perspective. Figure 5 reveals that, until recently, it was growth in government employment that fueled Swedish employment growth. Figure 6 shows that growth in employment, adjusting for population, lags the U.S. and the
OECD excluding the U.S.

Figure 4: PPP-Adjusted GDP per Capita in Sweden as Percent of OECD Average.

Source: Davis and Henrekson (2006).

Figure 5: Cumulative Employment and Population Change in Sweden, 1950–2004.

Source: Davis and Henrekson (2006).
Sweden is far from being a basket case. Capital taxation there is relatively low and was cut substantially in the reform of the early 1990’s. Levels of education are high. The international trade sector is competing effectively in world trade, especially in the Information and Computer Technology (ICT) sector, though it is dominated by a few big successful companies. Sweden’s world leadership in information technology comes largely from the success of a few established firms.

The partial reforms instituted in the Swedish economy in the past decade were effective. A lot of Swedish (and Finnish) growth is recovery growth—a rebound from a depression as deep as anything in the 1920s and 1930s. However, since the crisis of the early 1990s, Sweden has moved toward increasing incentives. This has helped to fuel growth.

Sweden has moved towards a more incentivized state. The introduction of incentives is an important ingredient of recent Swedish performance. However, a recent study concludes that there is still a lot of scope for reform and improvement in Sweden.⁴

Focusing on Sweden or the Nordic countries neglects the most vibrant European economy --- Ireland. Compared to Ireland, a country not often mentioned as a model for Europe by policy pundits, but much admired by many smaller Eastern European countries, the growth in employment in Sweden has been very limited. See Figure 7, which contrasts the GDP per capita growth of Ireland with that of the Nordics, and Figure 8, which contrasts Irish and Nordic civil employment growth and Figure 9, which compares Irish and Nordic productivity growth rates.

Put in context, the Swedish miracle is not so miraculous. Ireland substantially reduced taxes on capital, raised its educational stock and opened itself up to world trade. It is heavily unionized and follows a corporatist model. It was proper attention to incentives that produced the Irish miracle. Unlike the recent economic recoveries of Finland and Sweden, the Irish experience cannot be interpreted as a rebound from a deep depression in the 1980s. The Irish economy was stagnant for decades before the 1980s. As occurred in the reforms in Sweden, the U.K., New Zealand, Australia, Chile and Ireland, social partners cooperated in a time of crisis. It is important not to underrate the value of crises in producing reforms. The question is, can one avoid crises and still make meaningful reforms? I return to this question, but I first examine the official statistics that are the basis for the recent praise of the Nordic model more closely.

V. Understanding what the statistics reveal and conceal

The official statistics on Nordic welfare states are highly distorted. The lower levels of unemployment found there are misleading and conceal deep problems in those societies. Consider active labor market programs which are widely regarded in policy circles as a source of success of Nordic (and other) economies. There has been a substantial commitment to expenditure on active labor market programs (ALMP) in many European countries and especially in corporatist Europe. Figure 10 shows that ALMP programs account for more than four percent of GDP in some corporatist economies. The OECD (OECD, 2006) and many commentators have endorsed these programs in their official publications. They attribute lower unemployment in the Nordic areas in part to ALMP.
A large array of studies surveyed in Heckman, LaLonde, and Smith (1999) and Martin and Grubb (2001), as well as more recent studies, show that ALMP programs at current levels of funding have at best minor long term effects on wages and employment. Most do not survive a cost-benefit test. Few programs lift most participants out of poverty. A recent paper by Forslund and Krueger (2008) shows that none of the recent recovery of the Swedish economy can be attributed to ALMP programs.

ALMP accounting boosts reported Swedish GDP in a spurious way. Persons in training programs are counted as government employees and their wages are counted in Swedish GDP. This artificially inflates employment figures. Adjusting “open” unemployment by disguised unemployment produces a very different image of the performance of corporatist Europe compared to the performance of the U.S. than the image given in the official dialog on the success of the Nordic model. Figure 11 shows that, adjusting the padded statistics boosts corporatist unemployment rates by a full four percentage points. Adjusting European unemployment rates for ALMP substantially increases true European unemployment rates.
ALMP programs that conceal unemployment are only part of the reason for lower “open” Nordic unemployment rates. Europe, and Nordic Europe in particular, has many more persons dependent on government programs than the U.S. Consider just one program. Expenditure on disability is much higher in the EU than in the U.S. In Holland, at its peak, some 14% of all potential workers were collecting disability insurance. On top of the high expenditure on ALMP, expenditure on disability commands a substantial chunk of OECD expenditure. See Figure 13. The data for 2004 show that disability take-up rates among potential able-bodied workers reach levels as high as ten percent in many countries. See Figure 14.
More generally, dependency rates for social programs are much higher in the EU and the structure of dependency is different. Participation in welfare and transfer programs in the EU tends to be much more long-term than in other welfare states. In many EU states, the rate of dependency on transfers is high, and has increased. Participation in a variety of welfare state programs has produced lower rates of employment in many OECD countries. They reduce unemployment by buying people out of the workforce. When the data are adjusted for employment subsidies, the true employment rate of the corporatist states substantially declines (see Figure 15). The effects on Western welfare state employment rates are substantial (see Figure 16).
A larger fraction of the EU and especially corporatist EU employment is in the government sector (see Figure 17). Government employment is an index of regulatory activity and also in most sectors government employment is not productive although measurement of productivity in governments activity is a tricky issue.
The growth in dependency on government creates a serious problem of political economy in democratic welfare states. If one adds current dependents to government workers, one sees that there is considerable inertia to protect the status quo. Moreover, to finance the high level of benefits and the ALMP programs, tax rates are high. See Figure 18. The total share of spending on government is substantial, although it has begun to decline. See Figure 19. The disincentives for work and the timing of work over the life cycle and investment in human capital are substantial. Retirement benefits are perverse at a time when the population is ageing. It has been estimated that, in Denmark, for the median person, 75% of the taxes are repaid in benefits but both taxes and benefits distort margins throughout the lifecycle at many margins.\(^5\) Incentive schedules often create poverty traps.

\(^5\)See Bovenberg, Hansen, and Sørensen (2008).
There is an inverse relationship between the size of the government sector and the growth of GDP. See Figure 20. It turns out on closer analysis that transfers are the culprit, and not government expenditure per se. Recognition of the often harmful role of a large government sector, has led to trends in the OECD against public spending as is evident in Figure 19.

Figure 20: Correlation of growth and public spending - 30 OECD countries, 1960-2005.

Education is a major determinant of long run employment and unemployment. More educated workers are more adaptable, innovative and easily employed. Educational expenditure per student in tertiary education (college) is much lower in the EU than in the U.S. The relatively low rate of educational attainment in the OECD countries is due to (a) high progressive taxation of income with reduced incentives to acquire skills; and (b) exclusive reliance on public sector resources to support education at a time when government
resources are limited and fees are not charged and little reliance on the private sector as an engine of revenue as in the US. Student fees are a source of revenue and screen into schooling students with high demand for it. Joint ventures with business are limited. Sweden partially offsets this disincentive by generous subsidies to education. However, this policy runs the risk of training people for British, U.S. and Canadian jobs.

Figure 21: Proportion of 25-34 age group with university education

![Proportion of 25-34 age group with university education](source: OECD Education at a Glance, 2005.)

Figure 22: Real expenditure per student in US $

![Real expenditure per student in US $](source: OECD reports.)

Participation in generous welfare states leads to erosion of the work ethic and withdrawal from participation in the social compact. There is evidence of cohort drift in welfare participation. Those cohorts who have lived a greater fraction of their lives under the generosity of the welfare state come to accept its benefits and game the system at higher rates. Martin Ljunge (2006) has studied the use of sick leave for three cohorts of Swedes. The incentives to use the system have been the same for forty years. Yet as Figure 23 reveals, the take-up rate at the same age has increased for recent cohorts. This is a serious long-term problem for the European welfare state. Problems of an eroding work ethic are compounded
by the lack of assimilation of many immigrant populations. In truth, the welfare state creates inequality, and has self-perpetuating features.

Figure 23: Sick Leave Participation for Men and Women.

VI. Bad measures lead to weak conclusions; good measures lead to strong conclusions

The OECD and many students of European economic performance analyze the effectiveness of alternative economic systems by relating performance to various *ad hoc* measures of the incentives created by institutions. There is a large literature on cross-country panels that uses these measures to explain variation in European unemployment and other issues (see, e.g., Blanchard and Wolfers, 2000; Layard, Nickell, and Jackman, 1991). The countries studied are very heterogenous and the time series analyzed are typically very short. Many measurements of institutions are indices formed for entire countries. These studies do not analyze incentive effects on firms and workers at the levels at which the incentives operate. The analyses are conducted at aggregate levels using a “representative agent” framework that ignores basic heterogeneity in society. Such evidence is fragile and unreliable.

It would be fruitful for students of OECD labor markets to follow the lead of students of the Latin American labor market and quantify the costs and incentives of institutions governing labor markets (see the papers in Heckman and Pagés, 2004). Such studies would reveal the quantitative insignificance of the reforms made in Europe in the past decade. Scholars of Latin America have collected micro data on costs, employment, wages and turnover in their countries. Latin American countries have conducted many extreme policy experiments, which can teach lessons that can be transported elsewhere. Policy instability in the region produces some very crazy economic experiments with much greater variability than any natural experiments or policy experiments that have been observed in Europe. Many of these natural experiments are plausibly exogenous. From these experiments we can learn
about the basic economics of incentives. Consider the substantial variation in labor costs in Peru in the last decade associated with various Fujimori governments. Figure 24 shows the range of variation in non-wage costs due to policy shifts in Peru from the first quarter of 1987 to the first quarter of 1997.

Figure 24: Evolution of Non-Wage Costs Paid by Employers --- Peru.

Using these and other data, the costs of institutions (unions, labor market regulations, severance payment schemes, minimum wages) can be quantified and estimated on microeconomic models of firms. Translating regulations into costs allows analysts to summarize a variety of features of labor market institutions using an interpretable cost schedule. The cost data can be used to estimate the impact of regulation on the labor market. In the best studies, the analysis is highly disaggregated and applied to the firm or industry level.

Studies that measure labor cost precisely establish that labor demand curves are downward sloping, i.e., higher labor costs mean fewer workers demanded. This relationship has been found for economies around the world. The elasticity of demand for labor with respect to wage is 0.7.\(^6\) Regulations, unions and many institutions raise labor costs and reduce employment. A 10% increase in labor costs leads to a 7% reduction in employment. Contrary to folklore that many embrace because it is politically convenient to do so, binding minimum wages reduce employment as do payroll taxes that are imposed in countries without wage flexibility. The current practice of using ad hoc measures of the costs of institutions on highly aggregated statistics from very heterogenous countries is guaranteed to produce the finding that “institutions don’t matter” when in truth they do.

\(^6\)Hamermesh (2004).
VII. Payroll taxes

Payroll taxes reduce employment unless they are offset by public benefits that offset the tax cost, by downward wage adjustment or both. Payroll taxes are a substantial fraction of total labor cost in most modern welfare states. Disemployment effects of payroll taxes depend on what economists call “pass-through.” How much of the cost of a payroll tax is borne by firms and, therefore, how much disemployment is there, depends on how flexible wages are, and on how wisely funds are spent (do workers value the benefits?). One cost of corruption and bad governance is that firms bear a greater share of their payroll tax. This reduces employment.

VIII. Studies of union reforms corroborate the value of disaggregated studies

Consider the benefits of redefining the role of unions. Reforms of this nature have been put in place and analyzed using data at the individual plant level (see Nickell, Wadhwani, and Wall, 1992; Pencavel, 2004). These studies show the value of exploiting local knowledge and incentives. The more decentralized the locus of collective bargaining, the more economically productive is the worker-firm relationship and the less rent-seeking behavior there is by unions. Public policy toward unions should be even-handed and not favor one party over another. Governments should allow parties to set the rules and not impose uniform rules on all bargaining pairs.

One important exception to this rule is that, in times of crisis, it is possible—as in wartime—for centralized unions to act in the public interest and hold down wage demands. This observation motivates in part the claim of a “U” shape in optimal union density, i.e., that the best social arrangements are 0% union or 100%. Studies of unions find little evidence that monopoly unions operate in an enlightened fashion in the long run (see Pencavel, 1999). They can operate constructively in the short run in times of crisis but maintaining the cooperation in a period of sustained success has proved to be difficult.

Pencavel (1999) documents the effect of union reforms in the U.K. that moved bargaining to the local level. They raised productivity of firms (union and nonunion). The moral of Pencavel’s study is not to get rid of unions, but to change the union-firm relationship to focus on creating incentives to enhance productivity locally. Reforms in the union sector were complementary with product market reforms (see Pencavel, 1997, 1999). Uniform wage setting in Italy (south and north), East Germany and Northern Sweden that is not sensitive to local demands leads to high rates of unemployment in lower productivity regions.

IX. The burden of regulation

Many economies around the world operate under a heavy burden of regulation. These regulations raise adjustment costs of labor and promote inflexibility. Regulation leads to sluggish employment responses. Employment protection laws that are popular in LDCs and

Moreover, as noted by Nicoletti and Scarpetta (2003), product market and labor market regulation are highly correlated. (See Figure 25.) This array of regulations reduces innovation and impairs adoption of technology. (See Figure 26.) Regulation reduces entry of firms.\(^7\) (See Figure 27.) These barriers have substantial long-run, perverse effects on growth in productivity.

---

\(^7\)See Djankov, La Porta, Lopez-De-Silanes, and Shleifer (2002) and Freeman (2002).
X. The inequality argument for the welfare state re-examined

A principle argument in support of welfare states is that they reduce inequality and promote social inclusion. In practice, the welfare state often excludes people, creates inequality, and reduces competitiveness. The incentives in place often retard immigrant
assimilation and reduce inclusion. The rigidities of the welfare state raise lifetime inequality. Cross sectional inequality (over people at a point in time) is much larger in the U.S. than it is in Italy. The gap in lifetime inequality is much less (Flinn, 2002). Incentives to protect the status quo reduce mobility over the life cycle, and in other aspects of social life.

XI. Crisis is the Mother of All Welfare State Reforms

The political economy of the welfare state is rigged against reform because so many persons are its beneficiaries. Reforms that have occurred in most states have been quite modest. More drastic reforms are needed. Most of the reforms that have been put in place have come in the wake of an economic crisis. There is little internal capacity for democratic societies to reform themselves without a crisis. The welfare state can survive if incentives are adjusted.

In principle, as economists have long noted, society can undo one distortion with another. However, devising such incentives is complicated. The social system is delicate and the essential details required to offset one distortion with another are not really known well enough to plan with precision. As sixty years of political economy has shown, it is easy to create perverse incentives, and there are many examples.

XII. Summary

This paper seeks to elevate the discussion of the welfare state beyond the level of endorsing one system over another. I have presented the essential features that underlie the success of aspects of many different systems. Systems that respect the basic incentives of economic life are the most successful.

Incentives include rewards for production of output, for creation of new ideas and institutions; for work rather than politicking; incentives to seek jobs when economic conditions favor reallocations (e.g., sanctions in the Netherlands and Denmark); incentives to invest as opportunities arise, to venture, to build for the future; and incentives to move when economic conditions call for it (as in the flexicurity system).

Long-run trends in Western welfare states are not favorable even in the Nordic countries. This is especially clear once we move beyond the distorted statistics. High levels of taxation, protection and generosity of benefits erode the dynamism of a society. They build a culture of dependency that erodes innovation. They create a level of complacency that erodes the work ethic and mutes incentives to invest in skills and in the larger society. They create a system that protects the status quo and is very difficult to change except when a crisis emerges. In many states (e.g., Ireland, Finland, Holland, and Sweden) changes occurred only in moments of crisis.

There is much room for creative policy innovation. One can create incentives for mobility, but at the same time give workers some security as in the Danish “flexicurity”

---

8See, e.g., Atkinson and Stiglitz (1980).
system. One can create incentives to work (WTC, UK; EITC, US) and not participate in welfare. Such incentives boost productivity and raise levels of well-being and social integration. One can use social insurance accounts that insure, but at the same time introduce flexibility into the system.

The welfare state is a relatively new creation. It is not surprising that early versions of it sometimes created perverse incentives. Such perverse incentives are not intrinsic to it. Innovation, reform and experimentation will improve it. Attempts at reform and regulation should respect the power of incentives and promote efficient social insurance.
